# Intuition

Consider a situation where the untreated are very different from the treated:

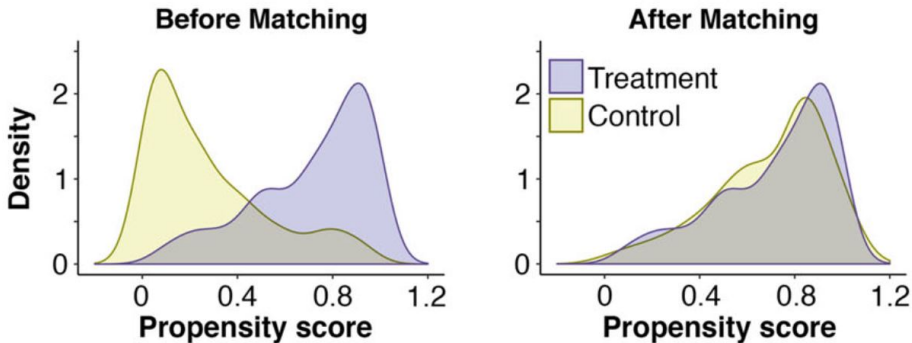

Image source: Schleicher et al. 2020

# Intuition

Consider a situation where the untreated are very different from the treated:

***Matching, def: any method that strategically subsamples dataset to balance covariate distribution in treated and control groups such that after matching both groups share an equal probability of treatment.***

**Non-Random  
Treatment  
Assignment**

**Matching Methods**  
→  
**to Subsample**

**Average Treatment Effect on  
the Treated + ~~Selection Bias~~**

Image source: Image source: Sizemore and Alkurdi 2019

# Intuition

    - or, at least, conditional unconfoundedness  $(Y(1), Y(0)) \perp T|X$
- $\pi(X_i) = Pr(D_i = 1|X_i)$  or *propensity score* can be used for matching
- but should maybe not (King and R. Nielsen 2019), we will see alternatives

# Overview

Here is a general overview of possible matching methods

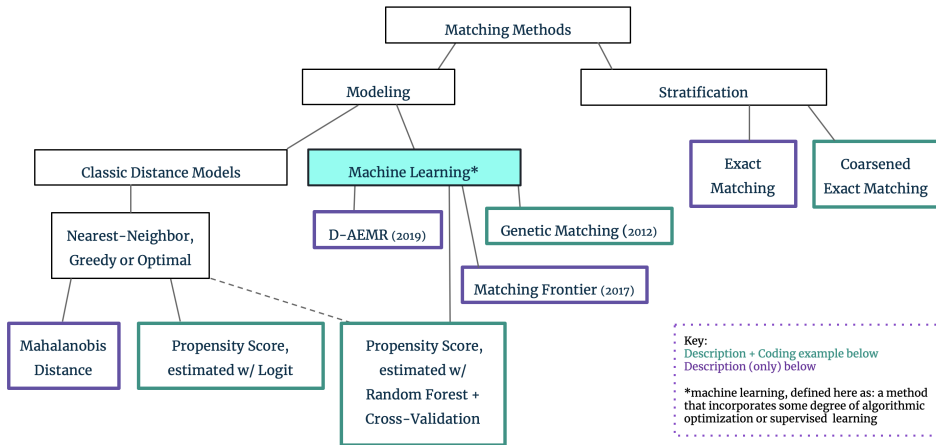

Image source: Sizemore and Alkurdi 2019

# Notation

## Introduction

## Matching

- exact match
- distance match
- machine-learning
- model comparison

## Synthetic Controls

- intuition

## References

Consider that we aim to estimate *conditional average treatment effect* (CATE) (cf. Abrevaya, Hsu and Lieli 2015)

$$CATE = E(Y(1) - Y(0)|X = x) \quad (1)$$

# Notation

## Introduction

## Matching

- exact match
- distance match
- machine-learning
- model comparison

## Synthetic Controls

- intuition

## References

Consider that we aim to estimate *conditional average treatment effect* (CATE) (cf. Abrevaya, Hsu and Lieli 2015)

$$CATE = E(Y(1) - Y(0)|X = x) \quad (1)$$

How to find the sufficiently similar subsamples?

# Notation

## Introduction

## Matching

exact match  
distance match  
machine-learning  
model comparison

## Synthetic Controls

intuition

## References

Consider that we aim to estimate *conditional average treatment effect* (CATE) (cf. Abrevaya, Hsu and Lieli 2015)

$$CATE = E(Y(1) - Y(0)|X = x) \quad (1)$$

King and Nielsen (2019) formulate a general pruning (*matching*) function  $M$ :

$$X_\ell = M(X|A_\ell, T_i = 1, T_j = 0, \delta) \equiv M(X|A_\ell) \subseteq X \quad (2)$$

providing  $X_\ell$ , subset of matched observation based on condition  $A_\ell$ .

# Notation

## Introduction

## Matching

exact match  
distance match  
machine-learning  
model comparison

## Synthetic Controls

intuition

## References

Consider that we aim to estimate *conditional average treatment effect* (CATE) (cf. Abrevaya, Hsu and Lieli 2015)

$$CATE = E(Y(1) - Y(0)|X = x) \quad (1)$$

King and Nielsen (2019) formulate a general pruning (*matching*) function  $M$ :

$$X_\ell = M(X|A_\ell, T_i = 1, T_j = 0, \delta) \equiv M(X|A_\ell) \subseteq X \quad (2)$$

providing  $X_\ell$ , subset of matched observation based on condition  $A_\ell$ .

→ in what follows we will look at different pruning method  $\ell$   
to produce the best matched subset  $\delta$ .

# Exact matching

## Introduction

## Matching

- exact match
- distance match
- machine-learning
- model comparison

## Synthetic Controls

- intuition

## References

For exact matching we find exactly equal pairs

$$X_{EM} = M(X|X_i = X_j) \quad (3)$$

*Note:*  $X$  can be a vector of covariates.

# Coarsened Exact Matching (CEM)

## Introduction

## Matching

- exact match
- distance match
- machine-learning
- model comparison

## Synthetic Controls

- intuition

## References

For coarsened exact matching we approximate

$$X_{CEM} = M(X | C_{\delta}(X_i) = C_{\delta}(X_i)) \quad (4)$$

where  $C_{\delta}$  is a vector of same dimensions as  $X$ , but coarsened values, e.g. at "*natural breakpoints*" such as years in one school type, levels of income, etc.

# Mahalanobis Distance Method (MDM)

For multidimensional data, we can identify nearest neighbours in an n-dimensional space.

## Introduction

## Matching

- exact match
- distance match
- machine-learning
- model comparison

## Synthetic Controls

- intuition

## References

$$md(X_i, X_j) = \{(X_i - X_j)^\top S^{-1}(X_i - X_j)\}^{\frac{1}{2}}$$

(Above) Mahalanobis distance measure, where  $S$  denotes the covariance matrix of  $X$ . [24]

(Left) A contour plot is overlaid on a Mahalanobis distance scatter plot of 100 observations randomly drawn from a bivariate normal distribution. The centroid, in blue, is the reference point for distance between two points.

Image source: Sizemore and Alkurdi 2019

# Propensity score matching (PSM)

Else, we can estimate probability of being treated, aka propensity score  $\pi(X_i) = Pr(D_i = 1 | X_i)$  by logistic regression

## Advantages

solves matching problem for high dimensions

many available R packages for easy implementation

## Disadvantages

misspecification of PS model = bad matches

matched pairs may be dissimilar across X

Image source: [Sizemore and Alkurdi 2019](#)

There is a bit of critique on PSM

- King and Nielsen (2019)
  - *"PSM is ... uniquely blind to the often large portion of imbalance"*
  - *"easy to avoid by switching to one of the other popular methods of matching"*
  - i.e.: CEM and MDM
- Sizemore and Alkurdi (2019)
  - test PSM against machine learning based methods
  - logistic PSM  $\succ$  random forest PSM  $\succ$  genetic matching
  - CEM ???

# Random forest (RF)

RF are multiple regression trees classifying the data by partitioning

Code source: [Wikipedia](#)

We can use this to predict treatment (aka propensity scores)

# eXtreme Gradient Boosting (XGBoost)

Machine learning such as XGBoost or even ensembles can also be used to

Code source: [Quant Insti](#)

→ predict treatment (aka propensity scores)

# Genetic matching

Genetic Matching combines PSM and MDM

$$GMD(X_i, X_j, W) = \sqrt{(X_i)^T (S^{-\frac{1}{2}})^T W S^{-\frac{1}{2}} (X_i - X_j)} \quad (5)$$
